Outline

- 1 Transition Systems as Kripke Models
- 2 Languages for Transition Systems
- 3 Properties of Transition Systems

Modeling the system: Kripke models

- **Kripke models** are used to describe **reactive systems**:
 - nonterminating systems with **infinite** behaviors (e.g. communication protocols, hardware circuits);
 - represent the **dynamic evolution** of modeled systems;
 - a state includes values to state variables, program counters, content of communication channels.
 - **can be animated and validated before their actual implementation**

Kripke model: formal definition

- A Kripke model $\langle S, I, R, AP, L \rangle$ consists of
 - a **finite** set of states S ;
 - a set of initial states $I \subseteq S$;
 - a set of transitions $R \subseteq S \times S$;
 - a set of atomic propositions (Boolean variables) AP ;
 - a labeling function $L : S \mapsto 2^{AP}$.
- We assume R **Total**: for every state s , there exists (at least) one state s' s.t. $(s, s') \in R$
- Sometimes we use variables with discrete bounded values $v_i \in \{d_1, \dots, d_k\}$ (can be encoded with $\lceil \log(k) \rceil$ Boolean variables)

Remark

Unlike with other types of Automata (e.g., Buechi), in Kripke structures the value of every variable is always assigned in each state.

Kripke Structures: two alternative representations:

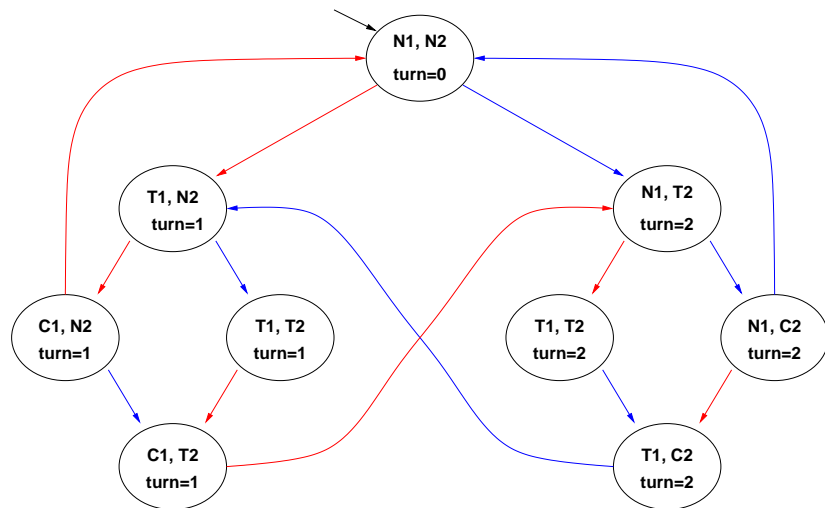

- each state identifies univocally the values of the atomic propositions which hold there
- each state is labeled by a bit vector

Other representations of finite state machines

- Moore machines
- Mealy machines
- Finite automata
- Büchi automata
- ...

Example: a Kripke model for mutual exclusion

N = noncritical, T = trying, C = critical

User 1 User 2

Path in a Kripke Model

A **path** in a Kripke model M is an infinite sequence of states

$$\pi = s_0, s_1, s_2, \dots \in S^\omega$$

such that $s_0 \in I$ and $(s_i, s_{i+1}) \in R$.

A state s is **reachable** in M if there is a path from the initial states to s .

Composing Kripke Models

- Complex Kripke Models are typically obtained by composition of smaller ones
- Components can be combined via
 - **asynchronous** composition.
 - **synchronous** composition,

Asynchronous Composition

- Interleaving of evolution of components.
- At each time instant, one component is selected to perform a transition.

- Typical example: communication protocols.

Asynchronous Composition/Product: formal definition

Asynchronous product of Kripke models

Let $M_1 \stackrel{\text{def}}{=} \langle S_1, I_1, R_1, AP_1, L_1 \rangle$, $M_2 \stackrel{\text{def}}{=} \langle S_2, I_2, R_2, AP_2, L_2 \rangle$. Then the asynchronous product $M \stackrel{\text{def}}{=} M_1 || M_2$ is $M \stackrel{\text{def}}{=} \langle S, I, R, AP, L \rangle$, where

- $S \subseteq S_1 \times S_2$ s.t.,
 $\forall \langle s_1, s_2 \rangle \in S, \forall I \in AP_1 \cap AP_2, I \in L_1(s_1) \text{ iff } I \in L_2(s_2)$
- $I \subseteq I_1 \times I_2$ s.t. $I \subseteq S$
- $R(\langle s_1, s_2 \rangle, \langle t_1, t_2 \rangle) \text{ iff } (R_1(s_1, t_1) \text{ and } s_2 = t_2) \text{ or } (s_1 = t_1 \text{ and } R_2(s_2, t_2))$
- $AP = AP_1 \cup AP_2$
- $L : S \mapsto 2^{AP}$ s.t. $L(\langle s_1, s_2 \rangle) \stackrel{\text{def}}{=} L_1(s_1) \cup L_2(s_2)$.

Note: combined states must agree on the values of Boolean variables.

Asynchronous composition is associative:

$$(\dots(M_1 || M_2) || \dots) || M_n = (M_1 || (M_2 || (\dots || M_n) \dots)) = M_1 || M_2 || \dots || M_n$$

Asynchronous Composition: Example 1

Asynchronous Composition: Example 2

Asynchronous Composition: Example 2

Synchronous Composition

- Components evolve in parallel.
- At each time instant, every component performs a transition.

- Typical example: sequential hardware circuits.

Synchronous Composition/Product: formal definition

Synchronous product of Kripke models

Let $M_1 \stackrel{\text{def}}{=} \langle S_1, I_1, R_1, AP_1, L_1 \rangle$, $M_2 \stackrel{\text{def}}{=} \langle S_2, I_2, R_2, AP_2, L_2 \rangle$. Then the **synchronous product** $M \stackrel{\text{def}}{=} M_1 \times M_2$ is $M \stackrel{\text{def}}{=} \langle S, I, R, AP, L \rangle$, where

- $S \subseteq S_1 \times S_2$ s.t.,
 $\forall \langle s_1, s_2 \rangle \in S, \forall I \in AP_1 \cap AP_2, I \in L_1(s_1) \text{ iff } I \in L_2(s_2)$
- $I \subseteq I_1 \times I_2$ s.t. $I \subseteq S$
- $R(\langle s_1, s_2 \rangle, \langle t_1, t_2 \rangle) \text{ iff } (R_1(s_1, t_1) \text{ and } R_2(s_2, t_2))$
- $AP = AP_1 \cup AP_2$
- $L : S \mapsto 2^{AP}$ s.t. $L(\langle s_1, s_2 \rangle) \stackrel{\text{def}}{=} L_1(s_1) \cup L_2(s_2)$.

Note: combined states must agree on the values of Boolean variables.

Synchronous composition is associative:

$$(\dots(M_1 \times M_2) \times \dots) \times M_n = (M_1 \times (M_2 \times (\dots \times M_n) \dots)) = M_1 \times M_2 \times \dots \times M_n$$

Synchronous Composition: Example 1

Synchronous Composition: Example 2

Synchronous Composition: Example 2 (cont.)

Description languages for Kripke Model

- Typically a Kripke model is not given explicitly, rather it is usually presented in a structured language (e.g., SMV, SDL, PROMELA, StateCharts, VHDL, ...)
- Each component is presented by specifying
 - **state variables**: determine the set of atomic propositions AP , the state space S and the labeling L .
 - **initial values for state variables**: determine the set of initial states I .
 - **instructions**: determine the transition relation R .

Remark

typically these description are much more compact (and intuitive) than the explicit representation of the Kripke model.

The SMV language

- The input language of the SMV M.C. (and NuSMV)
- Booleans, enumerative and bounded integers as data types
- now enriched with other constructs, e.g. in NuXMV language
- An SMV program consists of:
 - Declarations of the state variables (e.g., `b0`);
 - Assignments that define the valid initial states (e.g., `init(b0) := 0`).
 - Assignments that define the transition relation (e.g., `next(b0) := !b0`).
- Allows for both synchronous and asynchronous composition of modules (though synchronous interaction more natural)

The SMV language: example

Example: The modulo 4 counter with reset

```
MODULE main
```

```
VAR
```

```
  b0      : boolean;
  b1      : boolean;
  reset   : boolean;
  out     : 0..3;
```

```
ASSIGN
```

```
  init(b0) := 0;
  next(b0) := case
    reset = 1 : 0;
    reset = 0 : !b0;
  esac;
```

```
  init(b1) := 0;
  next(b1) := case
    reset = 1 : 0;
    reset = 0 : (b0 xor b1);
  esac;
```

```
  out := toint(b0) + 2*toint(b1);
```

The PROMELA language

- PROMELA (Process Meta Language) is the modeling language of the M.C. SPIN
- The syntax is C-like
- A system in PROMELA consists of a set of *processes* that interact by means of:
 - shared variables
 - communication channels
 - rendez-vous communications
 - buffered communications
- Processes can be created dynamically
- Allows for both synchronous and asynchronous composition of processes (though asynchronous interaction more natural)

The PROMELA language: example

Example: A Mutual Exclusion Algorithm

```
bool turn;
bool flag[2];
```

```
proctype User(bool pid) {
  flag[pid] = 1;
  turn = 1-pid;
  (flag[1-pid] == 0 || turn == pid);
  /* Begin of critical section */
  ...
  /* End of critical section */
  flag[pid] = 0;
}

init { run User(0); run User(1) }
```

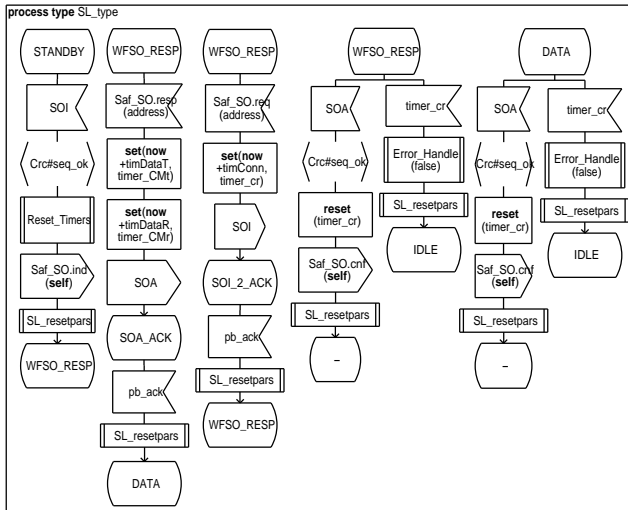

The SDL language

- An ITU standard
- Allows for booleans, enumerative and bounded integers as data types
- Allows for representing TIME (time elapse, clocks, ...)
- represents states, message I/O, conditions, clock operations, subroutines
- Allows for both synchronous and asynchronous composition of processes (though asynchronous interaction more natural)

The SDL Language: example

Example: the Safety Layer protocol

Safety properties

- bad events never happen
 - deadlock: two processes waiting for input from each other, the system is unable to perform a transition.
 - no reachable state satisfies a “bad” condition, e.g. never two processes in critical section at the same time
- can be refuted by a **finite** behaviour
- Ex.: it is never the case that p .

Liveness properties

- Something desirable will eventually happen
 - sooner or later this will happen
- can be refuted by **infinite** behaviour

Fairness properties

- Something desirable will happen **infinitely often**
 - important subcase of liveness
 - whenever a subroutine takes control, it will always return it (sooner or later)
- can be refuted by infinite behaviour
 - a subroutine takes control and never returns it
